What's New In RegDelNull?

RegDelNull is a command-line tool that helps you search for and allow you to delete a Registry key that contains embedded null characters. Null-embedded keys can be found using the Sysinternals RegHide, and deleting them via a standard Registry editor can cause some application to fail, as the VBScript that creates most security keys utilizes null-embedded characters. RegDelNull allows you to delete such keys completely. You need to know which keys you want to delete. That's where RegHide comes in. RegHide is a tool that uses static analysis to list all of the keys in a key-editing session. It also provides for a mode of operation that recursively scans sub-keys, and deletes them as well. In other words, the tool scans Registry keys for keys containing embedded null characters, and in some cases allows you to delete such keys. Note: deleting Registry keys may cause the applications they are associated with to fail. Thus, the tool does not function as a normal Registry editor. RegDelNull was written by Sysinternals.
